Links and Images

Hyperlinks

Hyperlinks in HTML (Hypertext Markup Language) are elements that allow users to navigate between web pages or different sections of the same web page. Hyperlinks are often displayed as text or images that, when clicked, direct the user to another resource. In HTML, hyperlinks are created using the **<a>** (anchor) element.

<a> Tag

Anchor tag or <a> tag is the most important tag while creating websites. It is used to connect different web pages. The <a> tag in HTML is used to create **hyperlinks**, allowing users to navigate to other web pages or resources by specifying the target URL.

Attributes of <a> Tag - There are three types of attributes in <a> tag.

a. herf
b. target
c. title

a. href- The "href" attribute in the <a> tag specifies the hyperlink's destination, defining where the link will take the user.

```
<a href="https: //example. com">Visit Example</a>
```

b. target- The "target" attribute determines how the linked resource will be displayed, such as in a new tab or the same window.

```
<a href="https: //example. com" target="_blank">Visit Example</a>
```

The **target** attribute can take the following values:

- **_self**: Opens the linked document in the same frame or window as the link. This is the default behaviour if the **target** attribute is not specified.
- **_blank**: Opens the linked document in a new browser window or tab.
- **_parent**: Opens the linked document in the parent frame.
- **_top**: Opens the linked document in the full body of the window.

c. **title-**The "title" attribute provides additional information about the link, visible as a tooltip when the user hovers over it.

<a href="https: //example. com" title="External Link">Visit Example</a>

The <a> tag enables the creation of hyperlinks using both text and images.

Let's explore an example based on hyperlinks to understand the attributes of <a> tag.

HTML Code	Output

`<body>`
 	
`<p>Visit my <a href="https: //www. example .com" target="_blank">example website </a>.</p>`
 	
`</body>`
	Visit my example website.

In this code the <a> tag is used to create a hyperlink. The href attribute specifies the destination URL, in this case,"https: //www. example. com". The text "example website" is the clickable link text that users will see. The target="_blank" attribute opens the link in a new browser tab.

Adding images to a web page

The <img> tag is used to add an image to a webpage, and it is a self-closing tag, that means it doesn't have a closing tag.

Syntax

```
<img src="abc.gif" >
```

This will add the image named abc.gif in your web page.

Attributes of <img> Tag- There can be five types of attributes in <img> tag.

a. src
b. alt
c. width
d. height
e. title

a. **src-**The "src" attribute in the <img> tag specifies the image source, indicating the file location.

```
<img src="image.jpg" alt="Description">
```

b. **alt-**The "alt" attribute provides alternative text for accessibility, describing the image content.

```
<img src="image.jpg" alt="Description">
```

c. **width & height-** "width" and "height" attributes determine the image dimensions, ensuring proper display on the webpage.

```
<img src="image.jpg" width="300" height="200"
alt="Description">
```

d. **title-** The "title" attribute in an image tag (<img>) provides additional information about the image.

```
<img src="image.jpg" alt="Description" title="Image
Title">
```

Now You also have the option to create a hyperlink using an image. In this case, you need to specify the image's name instead of text, let's learn an example to grasp how to utilize an image as a hyperlink.

HTML Code	Output

`<body>`
`<a href="fun1.html">`
`<img src="abc1.webp" alt="image not found"`
`style="width:100px;height:100px;">`
`</a>`	

The code has a clickable image that leads to "fun1.html" when clicked. The width and height of the image is set to 100x100 pixels, and if it can't be shown, alternative text the image is not found is provided.
